Effects of Dietary Marine Algae (*Spirulina platensis*) on Egg Quality and Production Performance of Laying Hens

N. Zahroojian¹, H. Moravej¹*, and M. Shivazad¹

ABSTRACT

In this experiment, a total of 128 Hy-line W³6½ hens at 63 weeks of age were used. The hens were put at random into 4 treatment groups (4 replicates and 32 hens per treatment) and were fed four different diets: three diets with different levels of Spirulina (1.5, 2.0 and 2.5%) and one control group based on wheat and soybean meal. All birds were housed in commercial cages, had ad libitum access to water, and were fed 100 g bird⁻¹ per day. Egg production, feed intake, feed conversion ratio, egg weight, yolk index, Haugh unit, shell thickness, shell weight, specific gravity, egg yolk cholesterol, and yolk color were compared with the control group. Egg yolk color was measured by the BASF Ovo-color fan. Our results indicated that these traits did not show any significant changes with the Spirulina addition (P> 0.05), while a significant increase in egg yolk color was observed in the treatments that received the Spirulina (P< 0.0001). Yolk color scores of the control group and different levels of Spirulina (1.5, 2.0 and 2.5%) were 1.5, 10.5, 11.4 and 11.6 in BASF color fan, respectively. There were not significant differences between the treatments with 2.0 and 2.5% of Spirulina. In conclusion, this study can suggest use of 2.0–2.5% of Spirulina in diet to produce an aesthetically pleasing yolk color.

Keywords: Natural pigment, Marine algae (*Spirulina platensis*), Yolk cholesterol, Yolk color.

INTRODUCTION

The blue-green algae, *Spirulina platensis*, have been used for hundreds of years as a food source for humans and animals due to the excellent nutritional profile and high carotenoid content. Spirulina is relatively high in protein, with values ranging from 55-65%, and includes all of the essential amino acids (Anusuya Devi et al., 1981). The available energy has been determined to be 2.5-3.29 kcal g⁻¹ and phosphorous availability is 41% (Lorenz, unpublished data, 2003, Available at: http://www.cyanotech.com/pdfs/spbul53.pdf). Chemical composition of *Spirulina platensis* is summarized in Table1 In poultry rations, algae up to a level of 5–10% can be used safely as partial replacement for conventional proteins (Spolaore et al., 2006). Prolonged feeding of algae at higher concentrations produces adverse effects (Spolaore et al., 2006). Spirulina is an excellent source of nutrition and provides a superior natural source of carotenoids that are extremely effective in coloring egg yolks (Lorenz, unpublished data, 2003). The yellow color of broiler skin and shanks as well as of egg yolk is the most important characteristic that can be influenced by feeding algae. In many markets, microalgae carotenoids are in competition with the synthetic form of the pigments (Spolaore et al., 2006). Although the synthetic forms are much less expensive than the natural ones, microalgae carotenoids have the advantage of supplying natural isomers in their natural ratio (Olaizola, 2003). In fact, 30% of the current world algal production is sold for

* Corresponding author: e-mail: hmoraveg@ut.ac.ir
animal feed applications and over 50% of the current world production of Arthrospira is used as feed supplement (Spolaore et al., 2006). Different studies have been conducted on the applications of algae in poultry nutrition and other animals (Anderson et al., 1991; Gouveia et al., 1996; Grinstead et al., 2000; Toyomizu et al., 2001; Regunathan and Wesley, 2006; Venkatesh Kumar et al., 2009). However, there are few researches about the use of Spirulina as a feed supplement in laying hens. The aim of this work is to study the effects of dietary marine algae (Spirulina platensis) as a feed supplement on egg quality and laying hen’s performance fed with diet based on wheat.

MATERIALS AND METHODS

Animals and Diets

A total of 128 Hy-line W36 hens at 63 weeks of age were used (the average weight of birds at the beginning of the experiment was 1500±40 g). The hens were put at random into 4 treatment groups (4 replicates and 32 hens per treatment) and were fed four diets: three diets with different levels of Spirulina (1.5, 2.0 and 2.5%) and one control group based on wheat and soybean meal without Spirulina in the ration. The composition of the control diet is shown in Table 2. Diets were formulated using UFFDA feed formulation package according to the nutrient requirements of white laying hens (NRC, 1994). Samples of the wheat, soybean meal, and wheat bran were ground in a laboratory mill fitted with 1-mm mesh.

screen. The dry matter (DM), crude protein (CP), ether extract (EE), ash and crude fiber (CF) contents of the ingredients which were used as feed were determined by the methods of AOAC (2000). The crude protein content of the samples was calculated from its nitrogen composition (N×6.25). The Ca and P contents were measured by flame atomic absorption spectrophotometry (atomic absorption flame emission AA670, Made in Japan) as an analytical technique (AOAC, 2000). Also, MEn were determined by prediction formulas based on the recommendation of the NRC (1994). The dry matter (DM), crude protein (CP), ether extract (EE), ash and crude fiber (CF), MEn, Ca, and P contents of the feed ingredient are presented in Table 3.

Statistical Analysis

The data were analyzed as completely randomized design, using analysis of variance procedures by the GLM procedure of statistical analysis software, SAS (2002). Differences between treatment means were tested using Duncan multiple comparison test and statistical significance was declared at a probability of P< 0.05 (Duncan, 1955).

**RESULTS AND DISCUSSION**

**Laying Hen Performance**

The results showed that egg production, feed intake, feed conversion ratio (FCR), and egg weight were not significantly affected by the dietary treatments (P> 0.05), (Table 4). In other words, Spirulina addition did not have any influence on production performance. These results are consistent with the results of other researchers that reported; Pigment
supplementation had not been associated with changes in production (Ross and Dominy, 1990; Garcia et al., 2002; Zahroojian et al., 2011). It seems possible that these results are due to the use of low levels of algae in those studies. However, Halle et al. (2009) observed a decrease in feed intake and no effect on the overall egg production with higher levels of algae. In contrast, in a field study, an increase of the laying performance of hens was observed, however, the hens used in that study were of low productivity (Janczyk, 2005). Also, several authors reported that laying hens fed Spirulina-containing diets attained the best means of egg production and feed conversion compared with those of the control group (Ross et al., 1994; Nikodémsz et al., 2010; Marley et al., 2012). In these experiments, the increase in egg weight for hens fed with the Spirulina-diets may be attributed to heavier egg yolks. Different results in these studies may be due to differences in strains of laying hens.

### Egg Quality Parameters

Egg quality measurements, after 4 weeks of feeding, are summarized in Table 5.

Yolk index, Haugh unit, egg yolk cholesterol, yolk color, shell thickness, shell weight and specific gravity were compared with the control group. Our results indicated that diets with Spirulina addition had no effect on egg quality parameters, except for yolk color score. These results are in line with those obtained by Inborr (1998) and Marley et al. (2012), who reported that there were no significant differences in egg shell percentage, yolk index, albumen percentage, and Haugh unit as a result of feeding experimental diets containing Spirulina. In contrast, Marley et al. (2012) reported that there were significant (P< 0.05) reductions in yolk cholesterol and total lipids as the level of dietary Spirulina was increased. This reduction in yolk total lipids and cholesterol contents may be related to their lower levels in blood plasma of hens fed with the Spirulina-containing diets (Marley et al., 2012).

The color scores of egg yolks of hens that were fed a diet containing Spirulina were higher than those that were fed a control diet. This result agreed with a previous study (Anderson et al., 1991). Also, it was reported that feeding Spirulina-diets achieved a significant increase in yolk color score (Sakaida, 2003; Marley et al., 2012) and egg yolk color score from quails fed dried Spirulina (Ross et al., 1994). The degree of yolk color preferred by consumers varies widely throughout the world, though deeper hues bring significant premiums in most markets. Baking operations and the food processing industry prefer darker colored yolks over adding artificial coloring agents. Although Spirulina powder appears as a bluish-green color, in fact, it contains one of the highest levels of carotenoids of any natural food source when properly manufactured and packaged (Miki et al., 1986). Yolk color scores of the control group

and different levels of Spirulina (1.5, 2.0 and 2.5%) were 1.5, 10.5, 11.4 and 11.6 in BASF color fan, respectively. The effect of Spirulina concentration on yolk color was better explained by polynomial effect response curves, as shown in Figure 1.

The optimal level of yolk color (between 11.4 and 11.6 on the BASF yolk color fan) was achieved with 2.0-2.5% Spirulina in diet after only 7 days, the color levels of the egg yolks remained stable as long as the supplementation continued (Figure 2).

There were no significant differences between the treatments with 2.0 and 2.5% of Spirulina.

In conclusion, this study can suggest use of 2.0~2.5% of Spirulina in the egg industry to produce an aesthetically pleasing yolk color without any negative effects on production performance.

Ditory Spirulina in Laying Hens

بررسی اثر جلبک دریایی/اسپیرولینا بر صفات کیفی تخم مرغ و عملکرد تولیدی تخم‌های تخم‌گذار

چکیده

در این تحقیق 128 قطعه تخم‌گذار نژاد های -لاین 16W در سن 63 هفته‌گی استفاده شد. مرغ‌ها به طور تصادفی در 4 تیمار (6 تکرار و 32 مرغ در هر تیمار) قرار داده شدند. مرغ‌ها با 4 جیره غذایی تغذیه شدند: یک جیره شاهد، یک جیره گندم و 3 جیره شامل یک جیره بخار و یک جیره بخار بندی‌های مختلف اسپیرولینا (2/5 و 2 درصد اسپیرولینا) بود. مرغ‌ها بطور آزاد به آب دسترسی داشتند و به هر مرغ روزانه 100 گرم غذا داده شد. تولید تخم‌مرغ، همراه با فرآیند ضربک خوراک، تخم‌مرغ، روزانه، شاخص زردِه، واحد هاو، ضخامت پوسته، وزن پوسته، وزن مخصوص تخم مرغ، کلسترول زردِه و رنگ زردِه در این آزمایش تعیین شد و با تیمار پایه مورد مقایسه قرار گرفت. رنگ زردِه بر اساس شاخص شرکت BASF اندازه‌گیری شد. نتایج نشان داد که صفات عملکردی مرغ‌های تخم‌گذار و همین طور صفات کیفی تخم‌مرغ تحت تأثیر جیره‌های آزمایشی قرار نگرفت (P≥0/05)، درحالیکه رنگ‌ زردِه در همه تیمارهای حاوی اسپیرولینا به طور معنی‌داری افزایش نشان داد (P<0/05). شاخص رنگ زردِه برای تیمار شاهد، درصد‌های مختلف اسپیرولینا (1/5، 1/10 و 5/20 به ترتیب، 1/5، 1/10 و 5/20 به ترتیب، 1/5، 1/10 و 5/20 به ترتیب، 1/5، 1/10 و 5/20 به ترتیب) بود. درصد‌های مختلف اسپیرولینا نظر رنگ‌ زردِه وجود دارد و در نهایت استفاده از یک اسپیرولینا در صنعت تولید تخم‌مرغ باعث تولید رنگ زردِه خوش‌این و مورد قبول می‌شود.
