Enhancing Growth, Yield, and Phytochemical Characteristics of Dracocephalum kotschyi Boiss through Optimized Planting Density

Sahar Zamani¹, Davood Bakhshi¹*, Mohammad-Taghi Ebadi², Amir Sahraroo¹, and Mehran Fathi¹

6 **ABSTRACT**

Dracocephalum kotschyi Boiss. is a medicinal plant used in various industries due to its high 7 health benefits, antioxidant activity, attractive flavor and aroma. Commercial yield and 8 phytochemicals can be enhanced by cultivation management like suitable plant density. This 9 study investigates the impact of planting density $(50 \times 40, 25 \times 40, 12.5 \times 40 \text{ cm} \text{ caused to } 5, 10, 12.5 \times 40 \text{ cm} \text{ cm$ 10 and 20 plants m⁻²) on the morpho-physiological traits, yield, trichomes, and phytochemicals 11 profiles of D. kotschyi, based on a Randomized Complete Block Design (RCBD) in the 12 Saravarsu region, Guilan province, Iran (2021-2022). The findings reveal a notable fourfold 13 increase in various traits in 20 plants m^{-2} (12.5×40 cm). The highest values for parameters such 14 as plant height (34.66 cm), branch number (14), branch length (9.34 cm), leaf number (138.33), 15 leaf area index (105 mm²), fresh weights of leaves, and stems, as well as total fresh weight 16 (105.1, 98.5, and 203.6 g m⁻² respectively), dry weights of leaves, stems, total dry yield (26.1, 17 24.675, and 50.775 g m⁻² respectively), chlorophyll a, b, total chlorophyll, and carotenoid 18 content (1.038, 0.653, 1.691, and 0.898 mg g⁻¹ FW, respectively), secretory trichomes density 19 (14 mm⁻²), essential oil content and yield (0.633% and 0.322 g m⁻², respectively), PAL activity 20 (10.221 nmol g⁻¹ FW min⁻¹), antioxidant activity (82.85%), total phenol (1.253 mg g⁻¹ DW), 21 and total flavonoid (2.781 mg g⁻¹ DW) were observed in 20 plants m⁻². In conclusion, a planting 22 density of 20 plants m⁻² (with spacing 12.5×40 cm) is recommended for achieving optimal 23 commercial yield, and phytochemical production of D. kotschvi in the Saravarsu region. 24

Keywords: Essential oil, Glandular trichomes, Medicinal plants, Cultivation management,
 Secondary metabolites.

INTRODUCTION

Medicinal and aromatic plants are rich Secondary Metabolites (SMs) sources, commonly referred as natural products, renowned for their divers' biological activities, and therapeutic effects in pharmaceutical, food, and cosmetic industries (Zamani *et al.*, 2021; Liu *et al.*, 2021).

Dracocephalum kotschyi Boiss is an endangered aromatic and medicinal plant belonging to 32 the Lamiaceae family, is renowned for its abundant essential oils (EOs) and flavonoids, 33 predominantly found in its aerial parts (Fattahi et al., 2013). The EO of D. kotschvi contains 34 compounds such as limonene, geraniol, citral, and perillaldehyde, while its methanolic extract 35 boasts phenolic compounds like xanthomicrol, luteolin, apigenin, cirsimaritin, and rosmarinic 36 acid (Fattahi et al., 2013; Heydari et al., 2019). Exhibiting a plethora of medicinal properties 37 including antimicrobial, anti-inflammatory, antioxidant, and anticancer effects, D. kotschyi is 38 also utilized for enhancing joint health, immune function, and memory (Zamani et al., 2023), 39 in addition to serving as a flavoring agent in food and tea (Zamani et al., 2023). 40

Optimizing planting density is vital for maximizing resource utilization and achieving peak 41 vield, a factor influenced by environmental conditions and plant species (Baloch et al., 2002). 42 43 Factors such as temperature, solar radiation, humidity, and soil fertility affect plant growth and nutrient requirements. Interspecies competition intensifies at higher densities, leading to 44 increased humidity, inadequate airflow, and reduced light penetration, thereby increasing the 45 risk of disease and reducing yield. Conversely, lower densities may lead to underutilization of 46 resources and decreased yield. Appropriate density enhances plant establishment, competition 47 against weeds, and light utilization efficiency, and ultimately improves yield and phytochemical 48 production (Copes and Scherm, 2005; Koocheki and Sarmadnia, 2012). 49

Numerous studies have examined planting density's effects on medicinal plants. Optimal plant 50 height, dry matter, and Essential Oil (EO) yield for Thymus daenensis and T. kotschyanus were 51 observed at medium to high densities (6 and 8 plants m⁻²) (Sepahvand et al., 2023). Satureja 52 bachtiarica Bunge exhibited increased yield but reduced trichome density and EO content with 53 higher planting density (Mirjalili et al., 2022). Higher plant density led to increase in fresh and 54 dry biomass as well as EO yield of Origanum vulgare (Gerami et al., 2018). Calendula 55 officinalis at a high density (57 plants m⁻²) exhibited maximal height, seed weight, chlorophyll, 56 EO content, and yield (Sepehri et al., 2016). Dracocephalum moldavica also demonstrated 57 enhanced growth and phytochemical production with increased density (Hashemian Ahmadi 58 and Hadipanah, 2014). 59

Hence, the current study was undertaken to investigate the influence of planting density onthe morphological traits, yield, and phytochemical compounds of the *D. kotschyi*.

62

63

65 MATERIALS AND METHODS

66 **Plant Cultivation**

D. kotschyi plants were cultivated in Saravarsu (50° 13' 26" E, 36° 49' 0" N, at 1,430 m) in
Rahimabad District, Rudsar County, Guilan Province, Iran. The climatic details of this region
are mentioned in Table 1.

Soil samples were obtained from a depth of 0-30 cm; and the physicochemical characteristics 70 are detailed in Table 2. The experiment followed a Randomized Complete Block Design 71 (RCBD) with three densities in three replications. Initially, the designated land was plowed and 72 enriched with 30 ton/ha cow manure. D. kotschyi seeds, sourced from Pakan Bazr Company in 73 Isfahan province, were germinated in a greenhouse during late winter. In spring, after levelling 74 the ground and creating ridges and furrows at 40 cm intervals, plots measuring 2×2 meters (4) 75 m²) were established. Seedlings, at the 6-8 leaf stage were transplanted to the main field. 76 Planting occurred with intervals of 12.5×40, 25×40, and 50×40 cm, equivalent to plant densities 77 of 20, 10, and 5 plants m⁻², respectively. Following planting, irrigation intervals were minimized 78 initially to aid plant establishment and prevent soil compaction. Subsequent irrigation schedules 79 were adjusted based on regional conditions and the plant's water requirements. Throughout the 80 growth phase, physical and manual weed removal practices were employed, and no instances 81 of pests or diseases were noted. 82

83

90

91

84 Morphological Traits Measurement

The aerial parts of *D. kotschyi* plants were randomly harvested from each plot at the full flowering stage (maximum phytochemicals accumulation). Plant height and branch length were measured using a ruler (cm). The branch and leaf number were quantified numerically. Leaf area index was calculated using grid paper. Yield indices, such as fresh and dry weights of leaves, stems, and total weight, were measured using a digital balance (g m⁻²).

Chlorophylls and Carotenoids Content

To measure chlorophyll and carotenoid content, 0.1 g of the sample was finely ground with 1 ml of 80% acetone, and the resulting mixture was refrigerated at 4°C in darkness for 24 hours. Subsequently the absorbance was recorded at wavelengths 470, 645, and 663 nm. The concentrations of chlorophyll a, chlorophyll b, total chlorophyll, and carotenoids were calculated using the formulas and reported as mg g⁻¹ of fresh weight (Lichtenthaler and Buschmann, 2001):

- 99 $Chl b (mg g^{-1} FW) = (21.5 A_{645} 5.10 A_{663}) (V/W 1000)$ (2)
- 100 Total $Chl (mg g^{-1} FW) = Chl a + Chl b$ (3)
- 101 Carotenoids (mg g⁻¹ FW)= [(1000 A_{470} -1.82 Chla-85.02 Chlb)/198] (V/W 1000) (4)
- 102 Which, V= Acetone Volume (ml) and W= Sample Weight (g).
- 103

104 Glandular Trichrome Density Measurement

Leaf samples measuring 2-3 mm² were cleansed with ethanol and distilled water. Subsequently, the dried samples were fixed on metal bases using conductive glue and coated with a thin layer of gold using a Coater (SBC121, KYKY Company, China). Finally, the samples were examined using a scanning electron microscope (SEM XL 30, Philips, Netherlands). Trichome density was determined by counting the number of trichomes within a 1 mm² area.

111

112 EO Content and Yield (EOC and EOY)

For EO extraction, 20 g of dried and powdered plant material was hydro-distilled using a Clevenger apparatus for three hours. The resulted EO samples were stored at 4°C until analysis (Zamani *et al.*, 2023). EO content and yield were determined using Equations 5 and 6, respectively:

117	EO content (%)= (EO weight/Dry matter weight)×100	(5)
-----	---	-----

118	EO yield $(g m^{-2}) = EO$ content×Total dry weight	/100 (6)
-----	---	----------

119

127

120 Phenylalanine Ammonia Lyase (PAL) Enzyme Activity

For enzyme extraction, 0.1 g of fresh plant material was homogenized in 1 ml phosphate buffer (pH= 7). Subsequently, 250 μ l of the enzyme extract was combined with 250 μ l of 10 mM sodium borate buffer (pH= 8.8), 250 μ l distilled water, and 250 μ l phenylalanine (50 mmol, 250 μ l) and read at 290 nm using a UV/VIS spectrophotometer (PG Instrument Ltd, Leicester, UK). PAL activity was determined by the Beer-Lambert law with an extinction coefficient of 9630 μ^{-1} cm⁻¹ and expressed as nmol g⁻¹ FW min⁻¹ (Saunders and McClure's, 1974).

Total Phenol Content (TPC), Total Flavonoid Content (TFC), and Antioxidant Activity (AOA)

TPC (mg Gallic acid g^{-1} DW) was quantified using methanolic extract (1:10) by the Folin-Ciocalteu method at 760 nm (Singleton *et al.*, 1999). TFC (mg Quercetin g^{-1} DM) was determined using the aluminium chloride method at 506 nm (Du *et al.*, 2009). The antioxidant

- activity was assessed using the DPPH (2,2-diphenyl-1-picrylhydrazyl) free radical method at
- 134 517 nm and determined as the percentage of DPPH inhibition using Equation (7) (Chiou *et al.*,
- 135 2007; Zamani *et al.*, 2023):
- 136 Free radical scavenging percentage= $[(A_{control} A_{sample})/A_{control}] \times 100$ (7)
- 137 A control: Absorbance of DPPH, A sample: Absorbance of plant extract+DPPH.
- 138

139 Statistical analysis

The experiment followed a Randomized Complete Block Design (RCBD) with three density treatments replicated three times. Mean data were compared using the LSD test at P< 0.01 that analyzed with SAS statistical software (Ver. 9). Correlation and regression analysis were performed using SPSS Ver. 26.

144

145 **RESULTS AND DISCUSSION**

146 Effect of Plant Density on the Morphological Characteristics of D. kotschyi

The plant density significantly influenced the plant morpho-physiological traits (P< 0.01) (Table 3). Increasing the density from 5 to 20 plants m⁻² resulted in a 2-3fold enhancement in the morpho-physiological characteristics of *D. kotschyi*. Specifically, the highest values for plant height (34.66 cm), branch number (14), branch length (9.34 cm), leaf number (138.33), and leaf area index (105 mm²) were observed in plants cultivated at a density of 20 plants m⁻². Conversely, the lowest density (5 plants m⁻²) exhibited the lowest values for the investigated indices (Figure 1).

Increased plant height due to higher plant density is linked to competition for solar radiation. 154 Dense plants populations reduce light penetration, triggering intensified competition for 155 sunlight. Additionally, under shaded conditions with limited light availability, the production 156 of growth hormones, such as auxin increases, resulting in heightened plant height (Arvin and 157 Firouzeh, 2018). Similar to our findings, the positive effects of increasing the cultivation density 158 on the plant height have been reported in ginseng (Liu et al., 2021), stevia (Btru et al., 2017), 159 and peppermint (Mansoori, 2014). In higher planting density, the number of plants per unit area 160 increases, resulting in a greater leaf count per unit area. In our study, an augmentation in plant 161 density resulted in an increased Leaf Area Index (LAI) in D. kotschvi plants. Optimal density 162 levels caused faster leaf growth and led to an augmented leaf area index. This increase in leaf 163 area positively impacts the photosynthesis rate, influencing various growth parameters, 164 including yield (Li et al., 2019). These findings align with research conducted on sunflowers 165 166 (Li et al., 2019) and marigolds (Sepehri et al., 2016). While greater spaces between plants (low

densities) lead to an average increase in individual development, but accompany with a decreasein the total potential yield (Moldovan *et al.*, 2022).

169

170 Effect of Plant Density on the Fresh and Dry Yield of the D. kotschyi

As indicated in Table 3, the plant density significantly affected the fresh and dry yield of the D. *kotschyi* (P< 0.01). Reduced planting intervals led to an augmentation in the fresh and dry matter of the D. *kotschyi* plant. The highest fresh weights of leaves, stems, and the total (105.1, 98.5, and 203.6 g m⁻², respectively) and dry weights of leaves, stems, and total biomass (26.1, 24.675, and 50.775 g m⁻², respectively) were observed at a density of 20 plants m⁻², which were 3-4 times higher than plants cultivated at a density of 5 plants m⁻² (Figure 2).

The correlation between higher plant density and increased biomass production, with peak 177 yield achieved at the highest density (20 plants m⁻²). Alteration in density affects various 178 factors, and in a density with minimized competition between the plants to receive moisture, 179 light and nutrients, maximum photosynthesis, photosynthetic pigments and growth is achieved. 180 This is the optimal density which leads to maximum yield and depends on the plant species and 181 environmental conditions. The increased density more than the optimum usually decreases most 182 growth parameters and photosynthesis (Dai et al., 2022; Sepehri et al., 2016). In Satureja 183 bachtiarica Bunge, the maximum plant yield was achieved at the highest plant density (80,000 184 plants/ha) (Mirjalili et al., 2022). Similarly, in Dracocephalum moldavica, an increase in the 185 plant density enhanced the weight with the highest fresh (8,260.2 kg) and dry vield (2,787.5 kg 186 ha⁻¹) were observed at a cultivation distance of 10 cm (Hashemian Ahmadi and Hadipanah, 187 2014). It was consistent with study on peppermint, where fresh and dry biomass yield and leaves 188 significantly increased with increasing plant density from 8 to 20 plants m⁻² (Mansoori, 2014). 189 Optimum plant density provides favorable condition, leading to increased dry matter 190 191 accumulation. This phenomenon is observed in medicinal plants such as Thymus daenensis (Jasemi et al., 2019) and Calendula officinalis (Sepehri et al., 2016). 192

Effect of Plant Density on Photosynthetic Pigments of the D. kotschyi

According to Table 4, the plant density treatment significantly influenced chlorophyll b, total chlorophyll, and carotenoid levels at a 1% significance level, however had no impact on chlorophyll a. The maximum chlorophyll a, b, total chlorophyll, and carotenoid content (1.038, 0.653, 1.691, and 0.898 mg g⁻¹ FW, respectively) were observed in the 20 plants m⁻² treatment, representing an increase of up to 3-fold compared to the lowest density. Conversely, the lowest pigment content was noted at 5 plants m⁻² (Figure 3).

193

Photosynthetic pigments, including chlorophyll a, b, and carotenoids, play direct and indirect 201 roles in photosynthesis, crucial for light absorption and energy regeneration (Tohidi et al., 202 2020). Consistent with our findings, planting density impacted photosynthetic pigments in 203 Perilla frutescens. Increased plant density leads to higher content of photosynthetic pigments 204 due to increased leaf number and area (as the source of photosynthetic pigments) (Wu et al., 205 2020). Thymbra spicata and Calendula officinalis showed higher chlorophyll a, b, and 206 carotenoid with increased row distance (Malekmaleki et al., 2022; Sepehri et al., 2016). On the 207 other hand, increased planting density (especially more than optimum density) reduced plant 208 photosynthetic capacity [net Photosynthetic rate (Pn)], stomatal conductance (Gc), and leaf 209 chlorophyll content (Dai et al., 2022). Additionally, Levisticum officinale and Coriandrum 210 sativum exhibited decreased chlorophyll with increased density (Atteya et al., 2021; Arvin and 211 212 Firouzeh, 2018). Generally, leaf pigment levels are influenced by factors like density, nutrition, species type, environment conditions, and diseases, impacting photosynthesis and yield (Tohidi 213 214 et al., 2020; Cui et al., 2018).

215

216

6 Effect of Plant Density on Glandular Trichomes of the D. kotschyi

Scanning electron microscope images revealed various types of trichomes in the *D. kotschyi* leaves including non-glandular (protective) and glandular (secretory) trichomes. Non-glandular trichomes were unicellular or multicellular, non-branched, sharp-pointed, bent, or erect types. Secretory trichomes were observed in two forms: peltate and capitate. In this experiment, nonglandular and glandular trichomes were observed in all three densities, but with an increase in cultivation density, the number of secretory trichomes increased from 10 numbers mm⁻² in the lowest treatment to 14 mm⁻² in the highest planting density (Figure 4).

Glandular trichomes, essential secretory structures in mint plants, are abundant in aerial 224 225 organs and play a crucial role in producing therapeutic compounds like terpenoids (EOs) and phenolic compounds (Feng et al., 2021; Tozin et al., 2015). Understanding their morphology 226 227 and response to factors like cultivation density is essential for medicinal plants, as changes in trichome structures and EO accumulation can occur due to environmental adaptations 228 (Tuttolomondao et al., 2016). In our study, an increase in plant density led to a higher number 229 of secretory trichomes on *D. kotschyi* leaves, likely due to the increased leaf number (providing 230 more space for trichome accumulation). Similar findings were observed in Artemisia cina, 231 where glandular trichome number correlated with leaf number (Herawati et al., 2020). In 232 Oregano, trichome density increased at the middle density (150×50 cm) but no significant 233 difference was noted across density levels (Tuttolomondao et al., 2016). Reports suggest that 234

high-density conditions, coupled with resource limitations like water, may induce slight stress, affecting trichome numbers. Glandular trichomes density of *Artemisia annua* increased with slight water stress (50% field capacity), while it decreased by 25% of the field capacity (Shi *et al.*, 2018). Optimal growth traits and secretory structure development were observed at a density of 20 plants m⁻². Overall, secretory trichome numbers are influenced by various factors, including growth conditions and plant species (Tozin *et al.*, 2015).

241

242 Effect of Plant Density on EO Content (EOC) and Yield (EOY) of the D. kotschyi

As indicated in Table 4, plant density significantly influenced both the EOC and EOY (P< 0.01). With an increase in plant density, both the plant EOC and EOY showed an upward trend. The maximum EOC and EOY (0.633% and 0.322 g m⁻², respectively) were recorded in the 20

246 plants m^{-2} treatment (Figure 5).

EOs valued for their diverse medicinal properties, have extensive applications across the 247 pharmaceutical, food, and cosmetic industries (Masyita et al., 2022). Increasing cultivation 248 density in Levisticum officinale led to higher EO content, with optimal yield obtained at a 249 distance of 15 cm (Atteya et al., 2021). Satureja bachtiarica showed increased EO yield at 250 higher plant densities (80,000 plants ha⁻¹) (Mirjalili et al., 2022). Dracocephalum moldavica 251 achieved the highest EO yield at a cultivation distance of 10 cm (Hashemian Ahmadi and 252 Hadipanah, 2014). EO content in Thymus daenensis and Calendula officinalis increased with 253 cultivation density (Jasemi et al., 2019; Sepehri et al., 2016). Higher planting density boosts 254 255 Essential Oil (EO) yield in savory plants due to elevated biomass production in dense conditions. Since EO is mainly stored in leaves and flowering branches, plants cultivated at 256 257 high density, yielding more leaves and flowering branches, also exhibit higher EO yield (Abbaszadeh et al., 2014). These findings are consistent with our observations. In Thymbra 258 259 spicata, a row distance of 20 cm resulted in the highest EO content and yield (Malekmaleki et al., 2022). Coriander plants exhibited increased EO content and yield with higher density (Arvin 260 261 and Firouzeh, 2018). Various physiological and environmental factors influence EO biosynthesis and accumulation, including geographical location, agricultural techniques, plant 262 type, and harvest time (Tuttolomondao et al., 2016). Plant density plays a crucial role in 263 maximizing crop quality, biomass, and EO yield, as observed in our study and others. 264

Effect of Plant Density on PAL Enzyme Activity and Antioxidant Compounds of the *D*. *kotschyi*

The plant density exerted a significant impact on antioxidant activity, total phenol, and flavonoid content (P< 0.05), but did not influence PAL enzyme activity (Table 4). As illustrated in Figure 5, the highest PAL activity (10.221 nmol g⁻¹ FW min⁻¹), antioxidant activity (82.85%), total phenol (1.253 mg g⁻¹ DW), and total flavonoid (2.781 mg g⁻¹ DW) were observed in the 20 plants m⁻² treatment. Conversely, the lowest the investigated traits were noted at a density of 5 plants m⁻².

Phenylalanine Ammonia-Lyase (PAL), a crucial enzyme, contributes to the formation of 277 278 antioxidant phenylpropanoid compounds like phenolic and flavonoid compounds which aid plant defense mechanisms (Zamani et al., 2021). These compounds have diverse biological 279 280 activities including antioxidant, antimicrobial, anticancer, and anti-inflammatory properties (Maina et al., 2021). PAL activity is influenced by various factors including nutrition, light, 281 environmental changes, density, stresses, etc. which can enhance gene expression, enzyme 282 production and phenolic productions (Zamani et al., 2021; Medda et al., 2020). Studies on 283 Linum usitatissimum L., have shown the increasing plant density enhances PAL enzyme 284 activity in specific cultivars (Gao et al., 2018). Alterations in planting density impact the 285 availability of growth factors, influencing plant competition for optimal growth and 286 subsequently phytochemicals such as phenolic compounds and antioxidants (Tazeh et al., 287 2016). Consistent with these findings, studies indicated a positive correlation between higher 288 plant density and elevated phenol and flavonoid levels, as well as increased antioxidant activity. 289 For instance, in ginseng, higher and medium planting densities were associated with the highest 290 ginsinoside production (Liu et al., 2021). Increasing planting density also led to an increase in 291 rosmarinic acid content in Perilla increases (Wu et al., 2020). In Levisticum officinale, total 292 phenol and antioxidant activities increased with higher density (Atteya et al., 2021). High 293 planting density in some studies limits several factors like light, water, and nutrients, and leads 294 295 to plant competition, and induced stress can stimulate PAL enzyme activity and alter phytochemicals (Maina et al., 2021). However, in our study, it seems that the high density of 296 297 plants provided the maximum availability of nutrients and the growth requirements of the plant, thus the plant has optimal growth, and it produces high phytochemical compounds. 298

300

Correlation and Regression Analysis of Measured Traits

Positive and significant correlations were observed among growth traits, yield, photosynthetic
 pigments, glandular trichomes and phytochemical traits in *D. kotschyi* (Table 5), which are

crucial for plant production and breeding programs. Elevated plant density led to increased 303 growth traits, positively correlated with yield, indicating the contribution of vegetative organs 304 to overall yield enhancement. Morpho-physiological factors showed a positive correlation with 305 photosynthetic pigments, influenced by increased leaf number and area (as the source of 306 photosynthetic pigments) due to density increment, leading to higher fresh and dry matter 307 production. A study on Levisticum officinale found a significant positive correlation between 308 growth characteristics, fresh and dry weight, and chlorophyll (Atteya et al., 2021). Additionally, 309 positive correlations were noted between fresh weight, dry matter weight, photosynthetic 310 pigment, and active substances (Table 5), suggesting enhanced pigment levels contribute to 311 increased biomass, enzyme activity, and phytochemical production. Similar findings were 312 observed in studies on *Mentha piperita* and *Satureja sahendica* Bornm, emphasizing the 313 importance of growth traits in Essential Oil (EO) production (Ostadi et al., 2023; Abbaszadeh 314 et al., 2014). Positive correlations between EO yield and overall fresh and dry yield were 315 reported in thyme (Sepahvand et al., 2016). Similar positive correlations between growth traits 316 and plant yield were also observed in Stevia Rebaudiana (Btru et al., 2017). Since secretory 317 trichomes are biosynthesis and storage places of essential oil, their density is positively 318 correlated with essential oil and is affected by several factors including planting density 319 (Esmaeili et al., 2019). In Origanum majorana, more and larger secretory trichomes with higher 320 EO content were observed in high light intensity (Shafiee-Hajiabad et al., 2015). Table 5 reveals 321 a positive correlation between the PAL enzyme and antioxidant compounds, emphasizing its 322 role in phenylpropanoid and antioxidant synthesis. Similar findings were reported by Zamani 323 et al. (2021) for Cynara scolymus, highlighting PAL's influence on phenylpropanoid 324 compounds. Atteya et al. (2021) found a strong positive correlation between phenol and 325 antioxidant activity in Levisticum officinale across various cultivation densities. Increased 326 density likely enhances antioxidant activity through elevated phenolic compounds, which 327 inhibit free radicals directly and enhance hydrogen donation potential (Ghimire et al., 2021). 328

The multivariate regression analysis was employed to explore the relationship between EO Yield (EOY), as a dependent variable (Y), and its affecting traits, treated as independent variables (X). The regression findings indicated that the Total Dry Weight (TDW) of the entire plant, with an explanation coefficient of 98%, and the EO Content (EOC), with an explanation coefficient of 94.8%, emerged as the most influential determinants of EOY (Equation 8): $Y = -0.232 + 0.005X_1 + 0.468X_2$ (8)

Where, Y= EO yield (g m⁻²), X₁= Total dry yield of the whole plant (g m⁻²), X₂= EO content (%).

Given that EO yield is affected by both plant dry weight and EO content, augmenting dry
weight and enhancing the EO content due to plant density has consistently resulted in
heightened EO yield, as shown in various studies (Ostadi *et al.*, 2023; Sepahvand *et al.*, 2016;
Abbaszadeh *et al.*, 2014).

341

342 CONCLUSIONS

- Based on the results, plant density significantly affected the most measured traits and the highest plant height, branch number, branch length, leaf area index, fresh and dry yield, photosynthetic pigments, secretory trichomes density, EO content and yield, PAL activity, antioxidant activity, total phenol, and total flavonoid were observed in high density (20 plants m⁻²). Generally, *D. kotschyi* plant cultivation with distances of 12.5×40 cm (a density of 20 plants m⁻²) due to the optimal growth conditions (nutrients, water, light, etc.), causes maximum growth and phytochemicals production. Therefore, this cultivation interval is recommendable
- 350 for the economic production of the *D. kotschyi* plant in similar ecological regions.

Table 5. Correlation between morpho-physiological and phytochemical traits of *D. kotschyi*.

*,**: Significant differences at 5 and 1%.

PLH: Plant Height; BN: Branch Number; BL: Branch Length; LN: Leaf Number; LAI: Leaf Area Index; LFW: Leaf Fresh Weight; SFW: Stem Fresh Weight; TFW: Total Fresh Weight; LDW: Leaf Dry Weight; SDW: Stem Dry Weight; TDW: Total Dry Weight; Chl a: Chlorophyll a; Chl b: Chlorophyll b; Chl t: Chlorophyll total; Car: Carotenoid; GTs: Glandular Trichomes; EOC: EO Content; EOY: EO Yield; PAL: Phenylalanine Ammonia Lyase enzyme; TPC: Total Phenol Content; TFC: Total Flavonoid Content; AOA: Antioxidant Activity.

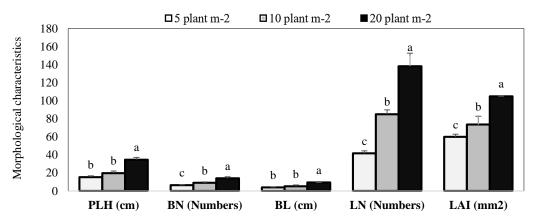

Figure 1. Morpho-physiological characteristics of *D. kotschyi* under different plant densities. PLH: Plant Height; BN: Branch Number; BL: Branch Length; LN: Leaf Number; LAI: Leaf Area Index. Means with same letters had no significant different at P< 0.01.

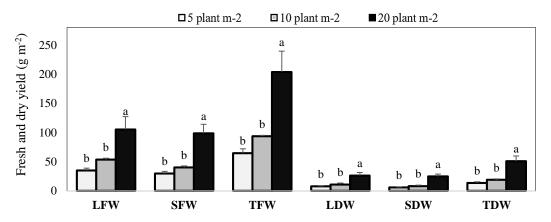

Figure 2. Fresh and dry yield of *D. kotschyi* under different plant densities. LFW: Leaf Fresh Weight; SFW: Stem Fresh Weight; TFW: Total Fresh Weight; LDW: Leaf Dry Weight; SDW: Stem Dry Weight; TDW: Total Dry Weight. Means with same letters had no significant different at P< 0.01.

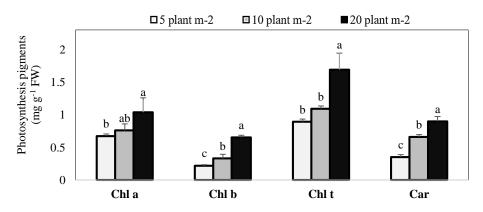

Figure 3. Chlorophyll and Carotenoid pigments of *D. kotschyi* under different plant densities. Chl a: Chlorophyll a; Chl b: Chlorophyll b; Chl t: Chlorophyll total; Car: Carotenoid. Means with same letters had no significant different at P< 0.01.

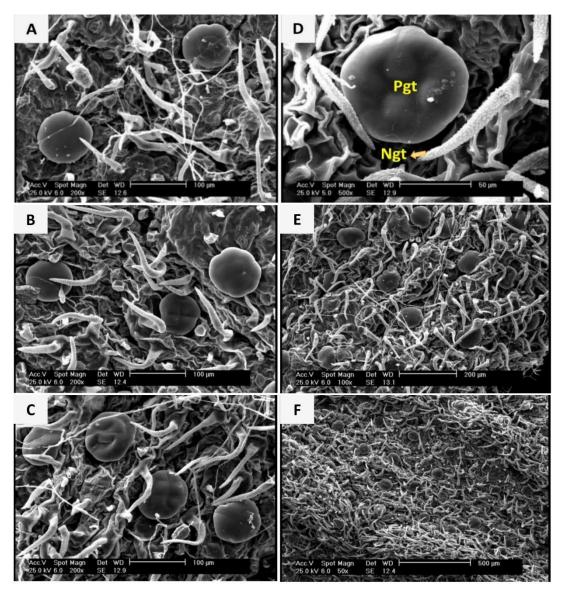

Figure 4. SEM images of *D. kotschyi* leaf under different plant densities. Distribution of Peltate glandular trichomes (Pgt), and Non-glandular trichomes (Ngt) of plants cultivated with densities at 5 (A, D), 10 (B, E), and 20 plant m^{-2} (C, F); Scale: A, B, C: 100 µm; D: 50 µm; E: 200 µm; F: 500 µm.

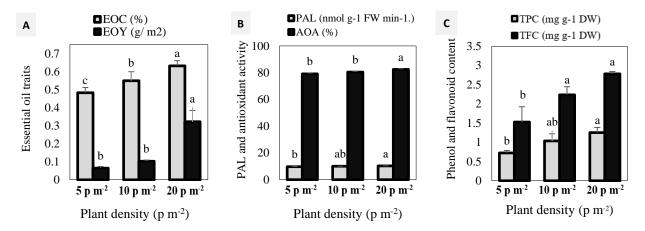

Figure 5. EOC (EO Content); EOY: EO yield (A); PAL: Phenylalanine ammonia lyase enzyme; AOA; Antioxidant activity (B); and TPC: Total Phenol Content; TFC: Total flavonoid content (C) of *D*. *kotschyi* under different plant densities. p m⁻²: Plant per m². Means with same letters had no significant different at P< 0.05.

افزایش رشد، عملکرد و ویژگی های فیتوشیمیایی زرین گیاه (Dracocephalum kotschyi Boiss) حاصل از تراکم کشت بهینه
