An Extension Model Compatible with Drought Management in Iran

Jalal Mahmoodzadeh[1], Mohammad Sadeq Sabouri[1]*, Mehrdad Niknami[1], Elham Danaee[1]

Abstract

The main purpose of this research was to design an extension model that is compatible with drought management in Iran. The research utilized a mixed research approach, combining both qualitative and quantitative methods. In the qualitative section, data was collected through semi-structured interviews, observation, and review of relevant sources. The participants in this section were 15 of extension experts with significant experience in drought management, selected through purposeful and snowball sampling methods. The data was analyzed using the systematic grounded theory approach with MAXQUDA10 software, following Strauss and Corbin's (1998) approach. In the quantitative section, the statistical population included experts, trainers, and professors whose field or organizational post is related to water resources, irrigation and drainage, Agricultural extension and development and drought which working full-time in the Ministry of Agricultural Jihad (N=6018). The sample size was determined using Cochran's formula, with a total of 372 participants. Structural equation modeling (SEM) and PLS software were used for data analysis. The results showed that the main components of the model were the detailed requirements of drought management (coefficient of 0.013), extensional methods of drought management (0.033), contextual conditions (0.1011), supporting conditions (0.166), conditions and causes (0.102), and consequences of drought management (0.065). Finally, an extension model compatible with drought management in Iran was presented.

Keywords: drought management, extension model, adaptation. Supporting conditions Contextual conditions

Introduction

Drought is an extreme climatic phenomenon that occurs throughout the world, especially in arid and semi-arid regions, with different intensities and leaves harmful effects on surface and underground water resources, agriculture, economy, and generally all aspects of life. Given Iran's location in the arid and semi-arid belt of the world, it is crucial to study drought as a widespread

[1] Department of Agricultural Extension and Education, Garmsar Branch, Islamic Azad University, Garmsar, Islamic Republic of Iran.

natural disaster with long-term effects in different sectors (Kheyri et al., 2021). It can be said that drought is a climatic reality in Iran, considering that 27 droughts have occurred in this country over the last 40 years (Zarafshani et al., 2016). Drought and its undesirable consequences for natural resources, agricultural production, and economic and social development are some of the fundamental challenges of Iran and drought-prone regions, and considering the frequency and significant extent of its occurrence, it is essential to implement directional mechanisms to counteract it (Savari & Skandari Damaneh, 2020; Solh & Van Ginkel, 2014). According to a UN report, 18 countries in the world will face water shortages in the near future, and it is predicted that more than two-thirds of the world's population will be in severe water shortage conditions by 2025 (Pozzi et al., 2013; Shabanali Fami et al., 2020). These disasters are partially caused by climate change (Rahman & Alam, 2016), and developing countries are more strongly affected by their risks than other regions due to deficient knowledge and adaptation to this phenomenon (Xenarios et al., 2016). The main climatic problem of dry areas is not the drought itself but the attitude toward it as an ordinary natural phenomenon and the lack of regulation of various water programs and uses based on that attitude (Khorambakht et al., 2013). Due to its biological nature and strong dependence on nature, agriculture is the largest consumer of water resources in most countries. In Iran approximately, 88% of water resources are used in agriculture (Pouralimoghaddam, 2022). Rural communities always face many effects of drought, including economic and social problems, which should not be underestimated, and a comprehensive approach is required to mitigate these impacts and achieve successful adaption (Kiem & Austin, 2013).

It is undeniable that various factors contribute to the occurrence of drought. On the other hand, it is beyond human capabilities to make changes or interventions in these factors to prevent them. Nevertheless, measures can be taken in different dimensions to cope with and reduce the negative consequences of drought. Water-intensive agriculture has suffered significant damage, resulting in the losses and degradation of rangelands and pastures and the decline in livestock numbers and productivity (FAO, 2017). Economically, drought imposes an annual loss of, on average, 6-8 billion USD globally, with adverse effects on farmers' revenue (production quantity and quality) being the most significant risk (Mardy et al., 2018). Consequently, it can be inferred that drought substantially threatens agriculture-based communities (Campbell et al., 2011; Fanni et al., 2016), impacting the productive, economic, social, and environmental sectors (Naderi & Karami Dehkordi, 2019). Various studies have indicated that drought has numerous social effects, including reduced social welfare, physical and mental health decline, increased social isolation, heightened conflicts, decreased trust and cohesion, lowered social capital, increased suspicion toward governmental institutions, longer working hours, decreased leisure time, increased divorce rates, and destabilized family systems, posing a fundamental challenge to farmers' livelihood stability (Keshavarz & Karami, 2010; Keshavarz et al., 2013). Therefore, communities exposed to drought are vulnerable to a lower standard of living (De Silva & Kawasaki, 2018). In this regard, improving farmers' capacity in areas like adaptation and resilience in climatic conditions is necessary to sustain livelihoods (Alam et al., 2016), along with strategies for adapting to water scarcity and drought conditions (Yazdanpanah et al., 2015). In this context, the overall objective of this research was to design a model of extension compatible with drought management in Iran.

Climate and environmental changes significantly impact the livelihoods of communities, especially in rural areas, and affect agricultural activities in different ways (Shakouri and Merseli, 2018). Therefore, farmers need to adopt behaviors compatible with the impacts of climate change to protect their livelihoods (Savari & Eskandari Damaneh, 2019) and minimize the adverse effects of these changes (Nilsen et al., 2012). Adaptation strategies consist of mainly medium- and long-term measures that farmers employ to improve the resilience of their farming units to drought-induced stresses (Ghambarali et al., 2012). Adaptation strategies are defined in risk management and crisis management (Kheyri et al., 2021; Tavakoli et al., 2015). In general, they encompass individual, economic, social, environmental, and institutional dimensions, which directly and indirectly affect agricultural production in both predictable and unpredictable ways (Smit & Pilifosova, 2003; Deressa, 2010; Ommani, 2011; FAO, 2012; Gomez et al., 2012; Feola et al., 2015). Therefore, in agricultural and rural areas, it is impossible to rely solely on agriculture to maintain production or improve people's lives. Instead, a wide range of drought adaptation strategies must be chosen (Thieme, 2006).

In order to face the effects of drought, farmers need to be empowered in various economic, social and technical dimensions, and in this regard, it seems that educational and extensional activities can be implemented to improve drought management by farmers (Arayesh, 2009). Agricultural extension services not only provide information on various aspects of items mentioned but help secure agricultural related services from banks, organizations and companies. The most important functions of agriculture extension services, however, are transfer of technologies and agricultural education of farmers to equip them with sufficient and suitable alternatives and solutions and place them in a decision making (Al-Zahrani et al., 2016). Optimal management, extension, and appropriate use of water in agriculture is essential. Agricultural education experts should implement, extensional programs to combat water scarcity at the national and provincial levels. These programs should cover producers of agricultural and horticultural products, as well as the implementing agents. By increasing knowledge and skills among producers and implementing agents, we can increase the efficiency of water resources and improve the quantity and quality of production in farms and orchards (Rahimian, 1395). One of the main challenges faced by water conservation experts is the lack of improvement in water management, particularly in irrigation, as well as the absence of proper organizations for farmers to promote their use of water. This is due to the farmers' lack of awareness about the water crisis and their disregard for it, as well as the insufficient knowledge of extension experts in providing effective plans. The low efficiency of irrigation in agricultural lands is also a result of the lack of timely and effective extension, leading to the waste of floodwaters. Furthermore, the absence of integrated water resource management plans in the watershed, and the lack of appropriate farming patterns in accordance with the sustainable capacity of water resources in the region, are also attributed to the lack of extension experts' knowledge. Additionally, the lack of awareness among beneficiaries about modern methods and the absence of specialized and knowledgeable experts in this field are also major issues (Hoseinzad et al., 1392). Therefore, presenting an extensional model for irrigation management and better coping with the drought in Iran, which leads to improved irrigation management, increased irrigation efficiency, and improved agricultural development, is of great importance. Table 1 provides a summary of studies regarding a extension and drought management.

Table 1. A summary of influential variables in a model of extension compatible with drought crisis management.

Research Title	Author	Method	Findings
Investigating the social consequences of drought on rural areas (case study: Shosef district, Nehbandan city)	Fal Suleiman et al. (2013)	Survey	In the environmental dimension, drought causes the drying up of surface water, the destruction of vegetation, and an increase in dust. In the economic aspect, the income level has decreased, the unemployment rate has increased, and agricultural and livestock production has decreased.
Extension pattern compatible with drought management in Razavi Khorasan Province, Iran	Mousavi et al. (2021)	Qualitative	Extension compatible with drought management requires cooperation and coordination between different institutions and organizations, and educational and extensional programs can significantly improve drought management.
Extension pattern compatible with drought management in Alborz province, Iran	Firouzjani (2018)	Qualitative	Planning, development, and implementation of water resources and drought management plans for each region should be based on the conditions and resources available in

Research Title	Author	Method	Findings
			that region. It is also essential to educate and promote concepts related to drought management.
Development of extension pattern for drought management in Iran	Rahimi et al. (2019)	Qualitative	Drought management requires the development of suitable extension models. Improving the awareness and capability of the society and water users in the field of drought management is one of the main success factors in the implementation of extensional models.
extension management using new media	Azari et al. (2017)	Qualitative	Teaching and extension the concepts related to drought management helps improve the awareness of society and farmers, improving drought management in Iran.
The perception of soil erosion and its social and economic factors in different regions of Sri Lanka.	Udayakumara et l. (2010)	Survey	agricultural workforce, household size, literacy rate, property security, conservation costs, promotional education, membership in local organizations, professional skills, financial capital, distance to land, and farm income are all important factors in understanding soil erosion in the studied region.
Drought management planning policy: from Europe to Spain	Hervás-Gámez & Delgado-Ramos (2019)	Qualitative	A key milestone in terms of European drought-risk management was set by the 2007 EC Communication "Addressing the Challenge of Water Scarcity and Droughts in the European Union". This presented an initial set of seven policy instruments for tackling water scarcity and drought issues at European, national, and regional levels. These included options in relation to 'putting the right price tag on water', 'allocating water more efficiently', and 'fostering water efficient technologies and practices'. The Communication also recommended the development of DMPs.
The Impacts of Drought and the Adaptive Strategies of Small-Scale Farmers in uMsinga, KwaZuluNatal, South Africa	Lottering et al.(2021)	Survey	Farmers adopted various adaptive strategies to adapt to drought such as the use of early-maturing crops, mixed cropping systems and drought-tolerant crops. With regard to mitigation, a majority of farmers did not prepare for drought, and those who did utilized indigenous methods of conserving water such as rainwater harvesting, the use of wells, and migrating for alternative employment.
Assessing agricultural drought management strategies in the Northern Murray–Darling Basin	Aitkenhead et al.(2021)	Qualitative	Government Assistance is the most used ADMS for Paroo Shire, the Maranoa Region and Murweh Shire, Whereas the MDB Plan is mainly used in the Goondiwindi Region.

Materials and Methods

This study used a cross-sectional methodology and a survey to gather descriptive data for a practical goal. Employing a mixed approach, incorporating both quantitative and qualitative methods (Johanson and Onwuegbuzie, 2004). In the initial stage of this research, data collection methods included semi-structured interviews, observation, and review of relevant sources. The systematic grounded theory with MAXQUDA10 software was used for data analysis and using Strauss and Corbin (1998) approach. For coding which includes three stages of coding: open coding, axial coding and selective coding (Lee, 2001; Creswell and Creswell, 2017). The qualitative section of the study included a sample of 15 senior experts and academic members with practical and scientific experience in drought (Table 2). They were selected using purposeful and snowball sampling methods.

Table 2. Frequency distribution of demographic and professional characteristics of the studied people.

Characteristic	Strata	Abundance
Age Average = 48.36	<30	1
	40-31	3
	50-41	6

	Agriculture extension	7
	agricultural development	3

Second stage, in this section Confirmatory factor analysis, structural equation modeling and Smart-PLS software employed. For this analyze, the statistical population consisted of 6018. Experts, trainers, and faculty members whose field or organizational post is related to water resources, irrigation and drainage, drought, Agricultural extension and development sciences which were employed full-time in the Ministry of Agriculture Jihad in Iran. The statistical sample was determined using Cochran's formula. The number of samples was determined to be 372 experts (Table 3). Sampling method was Stratified Sampling

Table 3: The number of samples in each of the three fields.

category	statistical population	Sample size
Experts	4390	271
Trainers and researches	930	57
faculty members	698	43
total	6018	372

Validity and Reliability

Guba, & Lincoln 1985 method was used to check reliability and validity. The indexes used were Dependability and Transferability. Based on this, re-coding was done in two different time periods and two other researchers were used. Based on the results, the Dependability index was 74% and the Transferability index was 71%. Considering that it was more than 60%, it can be said that the indicators had a favorable condition.

Confirmatory factor analysis was used within the SEM framework to assess the proposed model's validity (Nunnally & Bernstein, 1994, cited in Hosseinizare, 2017). To examine the reliability of the questionnaire, a pilot study was conducted with non-sampled respondents to make necessary revisions. The reliability or confidence level of the variables was estimated by Cronbach’s alpha coefficient (Table 4).

Table 4. Cronbach’s alpha coefficient for questionnaire factors.

Row	variables	Number of items	Cronbach’s alpha coefficients
1	management before drought	15	0/691
2	management after drought	11	0/701

7	disseminational and educational methods	12	0/754
8	Causal conditions	14	0/775
9	Contextual conditions of drought	12	0/811

Research findings

Examining the age of the responders showed that the highest frequency (36%) was related to the age group of 41-50 years. Also, 284 (76.3%) of the responders were male (the highest frequency), and 88 (23.7%) were female. In terms of the educational level, the highest frequency was related to the master’s degree with a frequency of 194 (52.2%). Among the study fields, agricultural engineering had the highest frequency of 165 people (44.3. Regarding experience, the highest frequency was related to 11-15 years with a frequency of 136 (36.5%. (Table 5).

In the structural equation model methodology, it is first necessary to study the validity of the structure in order to determine whether the indicators selected to measure the desired structures have the necessary accuracy. That is, have the questions to measure the variables been chosen correctly or not? For this purpose, confirmatory factor analysis (CFA) is used. In this method, the factor load of each indicator with its structure must be higher than 0.4.Factor loadings were calculated by measuring the correlation between indicator and connected construct. This suggests acceptable reliability regarding the measurement model (Table 6).

Table 6. Factor loadings under the modified components of the extension drought management model.

Factors	Manifesting variable	Factor loading
Contextual conditions	The presence of weather and climate information centers	0.731
	Information capacity of agricultural service centers	0.525
	The existence of agricultural and irrigation cooperatives	0.498
	The existence of training centers in the field of drought management	0.494
	Agriculture to financial resources	0.493
	Insensitivity of people and social networks	0.802
	Unauthorized exploitation of water resources	0.462
	The government's insensitivity to the issue	0.460
Causal conditions	Low level of education	0.455
	Weak financial base of farmers	0.447
	Weakness of water infrastructure	0.408
Intervening conditions	Crop insurance coverage	0.675
	Guaranteed purchase of agricultural products	0.671
	Investing in the infrastructure of irrigation networks	0.569
	Water pricing and sale	0.536
	Granting loans and free facilities	0.448
	Effective monitoring of the license of agricultural wells	0.447
	Supporting organizations and cooperative companies in the water sector	0.424
dissemination variables	Considering and measuring the educational- dissemination needs of farmers	0.612
	Using radio and television agricultural programs (mass media)	0.583
	Holding educational workshops	0.569
	Using dissemination personal messengers	0.558
	Using the Internet and virtual networks	0.516
	Visiting new irrigation systems	0.506
Consequences	Increase in fake jobs	0.905
	Reduction of cultivated area	0.903
	Decrease in income	0.808
	Insecurity	0.795
	Increase in input prices	0.790
	Reducing the price of agricultural land	0.730
	Decrease in production	0.713
	Decreased quality of life	0.707
	Decrease in welfare	0.598
	Reduction of local communication among people	0.591
	Increase in unemployment rate and immigration	0.582
Requirements for extension drought management	Assessing the educational- dissemination needs of farmers	0.842
	Providing extension specialist human resources	0.652
	Reforming the organizational structures of extension	0.591
	Reforming the financial structures of extension organizations	0.462
	Increasing the professional qualifications of extension agents	0.411

After ensuring the existence or non-existence of a causal relationship between the research variables and checking the appropriateness of the observed data with the conceptual model, the research hypotheses were also tested using SEM (the PLS approach). Table 7 and 8 depict the results of running model, and Tables 11 present the results of testing the hypotheses.

Table 7 shows the values of R^2 that represent the explained variance. Based on this, supporting conditions with a coefficient of 0.16 has the greatest effect and Consequences of drought with a coefficient of 0.06 has the least effect of Drought management. The total variables have explained 0.15 of the variance of the dependent variable.

Table 7. The measurement of the main model and the results of the hypotheses in the standard mode.

Variable	R^2	Path coefficient
Drought management (the dependent variable)	0.155	-
Detailed requirements of drought management	0.00	0.013
Extensional methods of drought management	0.00	0.033
Contextual conditions	0.00	0.1011
Supporting conditions	0.00	0.166
Conditions and causes	0.00	0.102
Consequences of drought	0.00	0.065

The values listed in Table 8 shows the T values. For each factor to be significant, the value of T should be significant at the error level of 0.05, that is, if its value is outside the range (1.96 and -1.96), the effect of this component is significant. Based on the listed results, all paths are significant (Table 8).

Table 8. The measurement of the original model and the results of the hypotheses in the standard mode.

Variable	T values
Drought crisis management (the dependent variable)	-
Detailed requirements of drought crisis management	4.874
Extensional methods of drought crisis management	2.207
Contextual conditions	2.094
Supporting conditions	4.661
Conditions and causes	4.812
Consequences of drought	2.029

The table 9 shows the factor loading values to answer the question of whether the questions to measure the variables are chosen correctly or not. To have the appropriate accuracy, the factor loading should be higher than 0.4. Based on the results listed in Table 9, most factor loadings are greater than 0.4.

Table 9. The measurement of the final model in the standard mode.

The effect of the independent variable on the dependent variables is depicted in Table 11. The significance coefficient (t-statistic) of the output model of SEM was used to test the research hypotheses. If the t-statistic was more than 1.96 or less than -1.96 (with a 5% error level), the hypotheses would be confirmed, and the significant effect of the variable would be achieved. It can also be seen in the measurement model that the factor coefficient for each variable is higher than the value of 0.50%. Table (11) presents a summary of the results of hypothesis testing.

Table 11. A summary of hypotheses testing results.

Hypotheses	Path coefficient	Significance coefficient	Result
Main hypothesis: Drought-adapted extension requirements affect agricultural drought management.	0.113	4.874	Confirmed
The first hypothesis: Extension methods affect the management of agricultural drought.	0.550	2.428	Confirmed
The second hypothesis: Contextual conditions affect the management of agricultural drought.	0.170	2.248	Confirmed
The third hypothesis: Causal conditions affect the management of agricultural drought.	0.440	3.719	Confirmed
The fourth hypothesis: The consequences of drought affect the management of agricultural drought.	0.001	2.008	Confirmed
The fifth hypothesis: Management policies affect the management of agricultural drought.	0.167	2.931	Confirmed

Table (12) presents composite reliability (CR), coefficient of determination (R^2), Cronbach's alpha, communality values, and communal reliability (AVE) for the main components of the research.

Table 12. The general model's quality criteria.

Research components	Composite reliability (CR)	Coefficient of determination (R^2)	Cronbach's alpha	Communal values (Cummunality)	Shared reliability (AVE)
Methods of extension drought management	0.76	0.58	0.84	0.49	0.43
Support policies	0.80	0.54	0.82	0.41	0.46
Contextual conditions	0.59	0.74	0.75	0.45	0.49
Causal conditions	0.71	0.83	0.88	0.31	0.54
Consequences	0.64	0.55	0.90	0.42	0.52
Background conditions	0.75	0.71	0.79	0.27	0.48
Drought management	1	--	1	1	1

To check the model's fit in PLS, we used the global quality criterion proposed by Amato et al. (2004).

$$\text{GOF} = \sqrt{\overline{communality} \times \overline{R^2}}$$

The index of fit of the general model (GOF) was 0.568%, so it can be accepted that the general model of the research has a good fit. The high fit of the model shows that this model is well explained (Table 13).

Table 13. The final model's fit

Index name	**R^2**	**Communality**
Methods of extension drought management	0.58	0.49
Consequences	0.63	0.52
Drought support policies	0.54	0.41
Background conditions	0.74	0.45
Causal conditions	0.83	0.31

Discussion and Conclusions

Agricultural sector requires specific adaptation to cope with water scarcity and drought (Yazdanpanah et al., 2015; Delphian, 2016). To address this challenge, an extension model should be designed based on local needs, culture, local language, and appropriate communication methods in each region to mitigate the negative impacts of these changes (Ifeanvi-obi et al., 2012; Engle, 2011).

Due to the level of knowledge and low adaptation to the phenomenon of drought, developing countries are more affected by the risks associated with it than other regions (Xenarios et. al., 2016). There are many reasons for this, including the lack of access to water and extension specialists, Lack of practical solutions for drought management and Lack of Extensional recommendations in drought management Also, the results of studies indicate an increase in the number of droughts in Iran (Firozi et al., 2019) In this case, there is a need for adaptation and drought management by farmers (karimi and atai, 2022) .The decision-making process around adaptation is complex (Bunham & Ma, 2016, Harmer & Rahman, 2014) and includes a wide and interconnected range of socio-political, social and environmental factors. Weather, its intensity and the level of confidence of farmers about receiving yield due to adaptation are closely related (Tucker et al., 2010; Anik et al., 2012). Therefore, it is important to extension drought management methods with the participation and cooperation of farmers. , which these methods include. People's participation in the adaptation of drought management is one of the necessary things in the success of programs in this field (Wani et al (2003). Blomley (2006) Ruiz-Malle´n et al., 2015). Publication of magazines, brochures, books, guidelines and Extensional books, about new methods of irrigation with traditional and old methods and comparing them in a demonstration for a group of farmers, Holding extension meetings with the presence of water and extension experts, Extensional exhibitions(New irrigation tools and methods) and, Extensional films and videos about new irrigation methods , Farmers visits to the office of the Agricultural Extension Service, Visit of agricultural extension workers to the farmers, Interaction with consulting service companies and extension organizations (Al-Zahrani et al., 2016). These activities are aimed at addressing informational and educational needs related to drought management (Harvey et al., 2014; Singh et al., 2017; Tripathi & Mishra, 2017). Such as to create these conditions need to Existence of extension specialists and access to them, Expansion of social networks and local networks to disseminate information.

Also Formation of agricultural cooperatives and water bodies In order to create irrigation groups, providing facilities in the field of extension services, Supportive policies in low water consumption (Cheng & Tao, 2010; Eriksen & Silva, 2009; Keshavarz & Karami, 2013). It can help a lot to establish a extension model that is compatible with the management of drought. In the end, it can be said that the establishment of this extension model can include: Increasing the resilience of farmers in dealing with drought, Access to meteorological and drought information, Access to drought management information, increasing participation of farmers in drought management.

(Figure 1) shows Extension Model Co

mpatible with Drought Management in Iran.

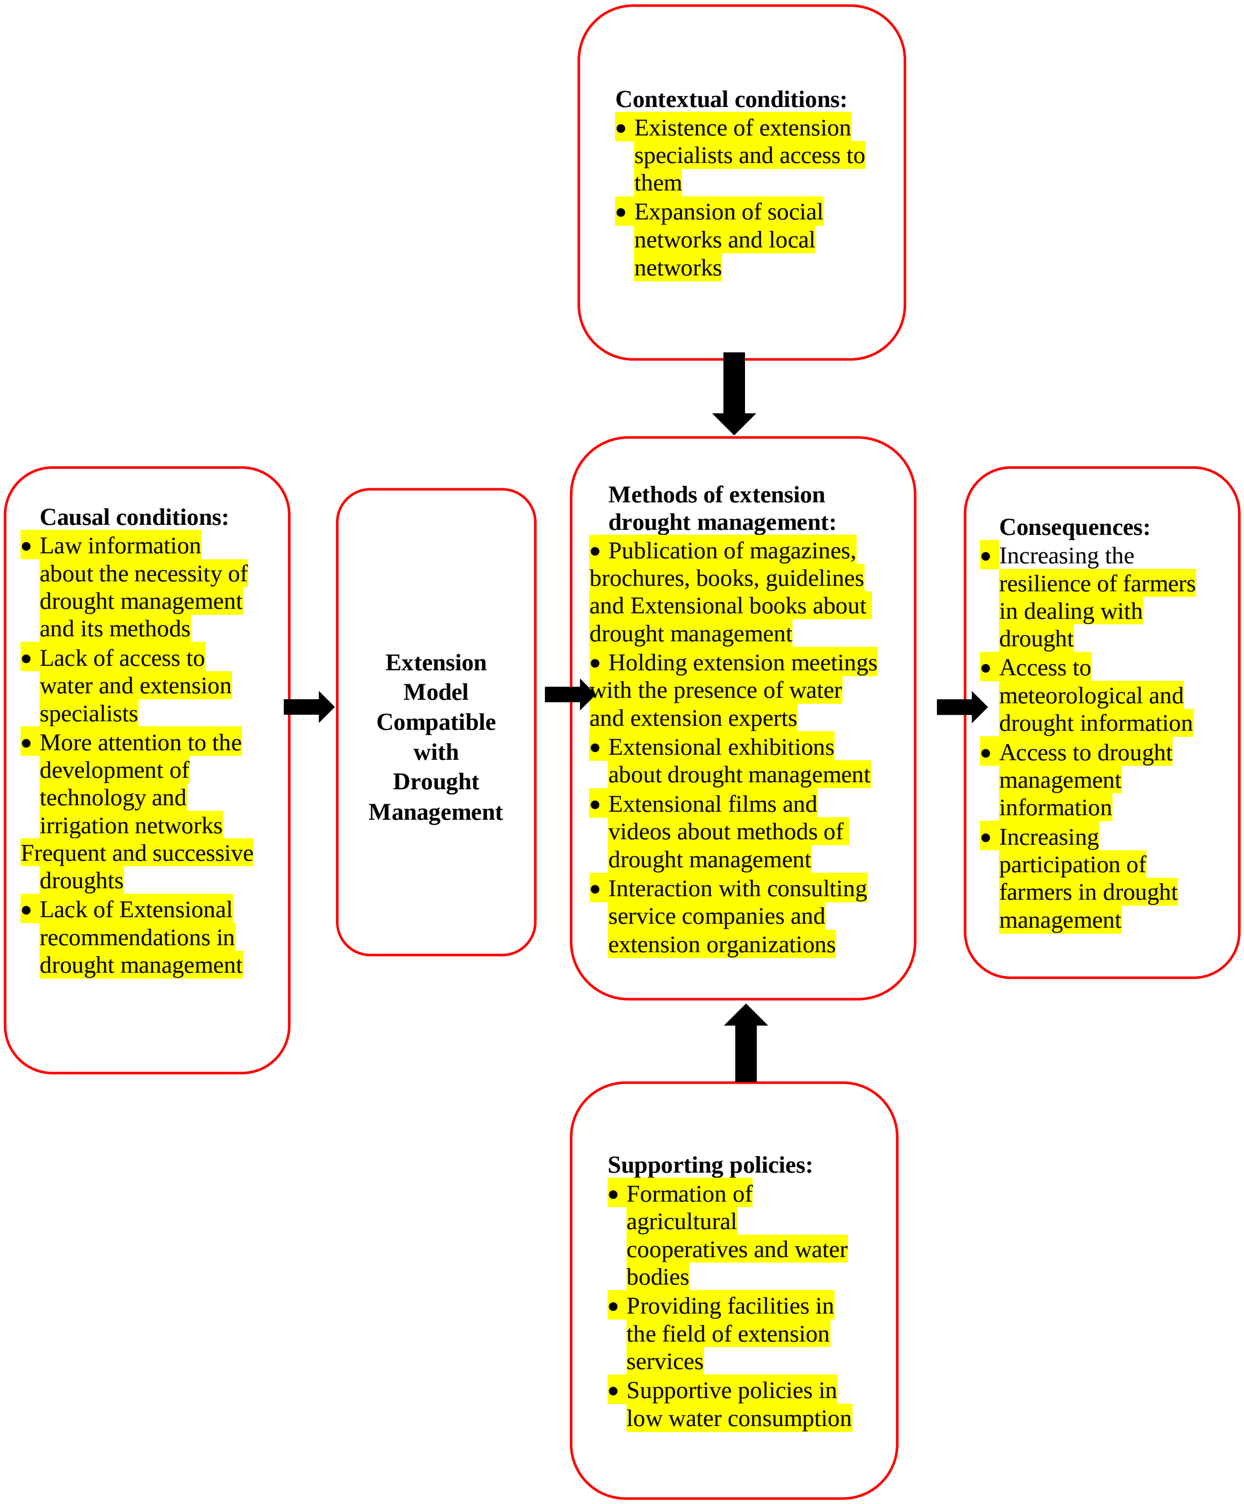

Figure 1. The final research model of the extension model compatible with drought crisis management.

Recommendations

Based on the results, it is recommended to involve knowledgeable agricultural extension experts in providing necessary training and technical advice to farmers. It will be helpful to establish constructive communication between farmers and extension agents through social networks to address existing water-related issues and convey them to relevant authorities for appropriate solutions. Also, the importance of water and the impact of water scarcity challenges on economic, social, and security sectors should be recognized. Additionally, it is necessary to prioritize this issue as a fundamental strategy in the annual budget and Iran's Seventh Development Plan. Last but not least importantly, it is recommended that the government support farmers through facilities such as low-interest loans and subsidies to assist in implementing adaptation strategies and drought management.
