Exploring factors affecting the Pastoralists Resilience against Climate Change

Amir Keivan Darvish¹, Maryam Omidi Najafabadi¹, Seyed Mehdi Mirdamadi¹, Seyed Jamal Farajollah Hosseini¹

Abstract

Climate change (CC) is one of the major challenges of our time that impacts rangelands regionally and globally. The rising vulnerability among pastoralists highlights the need to prioritize resilience thinking. Pastoralists' resilience refers to the ability of rangeland businesses to endure, adapt to, and remain flexible in the face of threats or challenges. This research was conducted with the primary goal of analyzing the factors that influence resilience from the perspective of pastoralists in Tehran province under CC conditions. This research was both goal-oriented and exploratory in methodology. The study sample consisted of 317 pastoralists selected through stratified random sampling. The data collection tool was a researcher-made questionnaire. Software SmartPLS was used for data analysis. The validity of the questionnaire was assessed using the average variance extracted, while its reliability was established by calculating composite reliability and Cronbach's alpha. Data were analyzed using the structural equation modeling technique with Smart PLS software. The structural equation modeling indicated that economic, institutional, ecological, physical, social, educational and extensional and individual factors had the greatest impact on Pastoralists' Resilience under Climate Change (PRCC) conditions. These factors explained 75.5% of the PRCC conditions.

- **Keywords:** Resilience, Pastoralists, Climate Change.
- Abbreviations: Pastoralists' resilience under climate change: PRCC; Resilience Capacities under Climate Change Condition: RCCCC; Climate Change: CC.

Introduction

Pastoralism in the Zagros Mountains began approximately 9,000 years ago and is globally significant for its contributions to food production, ecosystem services, livelihoods, culture and civilization; to make a living, Pastoralists care for, maintain and use livestock in rangeland areas under unpredictable weather conditions (Dong et al., 2016). Today, rangeland degradation is a

In Press, Pre-Proof Version

global issue that not only threatens the existing plants and animal populations, but also human 31 communities (Husein, 2021). CC is one of the factors contributing to rangeland degradation in 32 33 many parts of the world (Angerer et al., 2023). CC causes alternations in temperature and precipitation in a region (Brêda et al., 2020). In semi-34 arid areas, vulnerability and food security pose significant challenges (Raj and Sharma, 2023). Iran 35 is located in one of the driest regions of the world and has been affected by CC in recent years, 36 37 particularly by drought (Bahrami et al., 2021). In Iran, rangelands cover is approximately 55 percent (Sadeghi and Hazbavi., 2022) Pastoralists 38 identified three factors of reduced forage quality, increased barren land and reduced livestock 39 production as the most important impacts of drought on rangelands (Behmanesh et al., 2021). 40 41 The rangelands of the province of Tehran, beingin a critical state of destruction (Yousefi et al., 2021) has not been spared from Meteorological station data (2001-2021), which indicates the 42 phenomena of CC and drought (Javadi et al., 2024). These issues have led to reduced forage 43 production in rangelands, making it more difficult for pastoralists. Consequently, pastoralists have 44 45 been compelled to overgraze beyond livestock capacity of the rangelands. This has also led to degradation of these areas (Yousefi et al., 2021). 46 47 There is an agreement among experts that problems cannot be solved solely through technical innovations, policy reforms or economic development; new researches and monitoring programs 48 49 need to be designed for pastoralists that might address ecological, social and economic interdependencies within resilience frameworks (Dong et al., 2016). 50 There is no consensus among experts on the concept of resilience. Resilience has been defined 51 differently in various disciplines over time. Holling first introduced this term as an ecological 52 concept in 1973 (Holling., 1973). In the recent decades, this concept has emerged in the literature 53 on socio-ecological systems and rangeland management (Dong et al., 2016; Kapruwan et al., 54 55 2024). The adaptive cycle illustrates how this system maintains its activities or quickly regains its previous state when faceed with external shocks such as drought. However, these shocks and 56 stresses may lead to new approaches or cause a socio-ecological system to be distrupted or 57 abandoned (Meuwissen et al., 2019). If the pastoral system is not resilient, it is likely to disappear 58 because it cannot guide itself through the adaptive cycle. Resilient pastoralists, when faced with 59 challenges such as drought, attempt to steer the current situation toward improvement and positive 60 outcomes by adopting logical and effective solutions. 61

In Press, Pre-Proof Version

Given the challenges and problems raised by CC, the most important issue is finding solutions that 62 can improve the lives of pastoralists. This is because pastoralists are major food producers who 63 are highly vulnerable and possess low recovery capacity due to their dependence on the 64 environment, particularly under conditions of CC and drought. Therefore, it is necessary to take 65 significant steps by developing effective strategies in the CC management process such as adopting 66 a resilience approach. Various dimensions, indicators and variables related to resilience can be 67 68 discusse, some of the most important of which have been addressed. Meuwissen et al. (2019) proposed that distinguishing three resilience capacities can help evaluate 69 a wide range of resilience strategies. Adzawla et al. (2020) argued that factors such as education, 70 income, etc. are effective in promoting resilience. Ahmad and Afzal (2021) asserted that access to 71 72 services is one of the key factors influencing resilience. Melketo et al. (2021) found that savings, 73 livestock diversity and similar resources contribute to improved resilience. Le Goff et al. (2022) 74 also believed that farmers maintain their resilience through mutual community interactions and institutional support under various conditions. Finally, Kapruwan et al. (2024) carried out a 75 76 research in India and found that promoting and strengthening organizational structures enhances communityresilience to CC. 77 Programs and strategies for rangeland climate are more effective when they are tailored to local 78 conditions. Opinions of local rangeland advisers are crucial for the development of these resources 79 80 (Dinan et al., 2021). Localization was achieved through a systematic review. Research findings were systematically analyzed using Sandlowski and Barroso's seven-step method. The findings of relevant 81 domestic and international researches were thorouly assessed using the seven-stage method of 82 Sandelowski and Barroso. The Waltz and Bausell method was employed to evaluate the validity of the 83 extracted data. The reliability was also assessed through the Kappa coefficient, yielding a value of 0.87, 84 indicating an excellent agreement (Darvish et al., 2023). 85 According to the various studies done, several factors influence the PRCC. Proper management of 86 these factors improves Resilience. Resilience is the capacity of pastoralists to cope with CC. It has 87 been measured through indicators of robustness, adaptability, and transformability. 88 By studying former research, the following hypotheses can be considered in the current study: 89 1. Individual factors significantly influence the resilience of pastoralists in Tehran province under 90

CC conditions.

In Press, Pre-Proof Version

- The individual factor includes a sense of self that the pastoralist has, and guides itself in the right
- 93 direction when faced with CC. This factor is measured in terms of psychological indicators (CD-
- 94 RISC), health and family.
- 95 2. Educational and extension factors significantly influence the resilience of pastoralists in Tehran
- 96 province under CC conditions.
- 97 The educational and promotional factors encompass educational and technical support provided
- by the extension sector, which enhances the attitude, insight, knowledge and skills of pastoralists
- 99 in response to CC conditions. This factor is measured by two indicators of education and extension.
- 3. Social factors play a significant role in the resilience of pastoralists in Tehran province under
- 101 CC conditions.
- These social factors include the feelings that pastoralists gain from their society-such as their
- perception of other pastoralists, their sense of responsibility toward one another, the trust they have
- in each other, and their understanding of the social structure that guides them in effectively facing
- 105 CC. This factor is comprising indicators of social security, social participation, social trust and
- social coherence.
- 4. Economic factors significantly influence the resilience of pastoralists in Tehran province under
- 108 CC conditions.
- The economic factor pertains to the assets of pastoralists and their access to the resources needed
- to engage in resilience activities in the face of CC. This factor is measured in terms of job and
- income indicators, financial support, and economic capability.
- 5. Physical factors play a significant role in influencing the resilience of pastoralists in Tehran
- province under CC conditions.
- The physical factor refers to pastoralists' access to communication infrastructure necessary for
- their activities, etc. This factor has two indicators: access to infrastructure and machinery.
- 6. Ecological factors significantly influence the resilience of pastoralists in Tehran province under
- 117 CC conditions.
- The ecological factor refers to pastoralists' access to natural resources and their enhancement to
- sustain pastoral activities. Indicators of this factor include ecological assets and the protection of
- 120 natural resources.
- 7. Institutional factors are crucial in shaping of the resilience of pastoralists in Tehran province
- under CC conditions.

The institutional factor pertains to government governance, which plays a fundamental role in improving the conditions for PRCC conditions. Government laws and regulations, government support, and the relationship between the government sector and pastoralists are effective in increasing PRCC (pastoralists' resilience to climate change). This factor comprises indicators related to institutional context, institutional relations and institutional coherence.

Based on prior research, including studies by Meuwissen et al. (2019) and Darvish et al. (2023), the conceptual model for the present study has been developed. it features seven variables and 21 components, as illustrated in Figure 1. The seven factors - individual, educational-extensional, social, economic, physical, ecological and institutional – will collectively influence the resilience of pastoralists. Robustness, adaptability and transformability are outcomes of resilience that arise from the conditions related to PRCC.

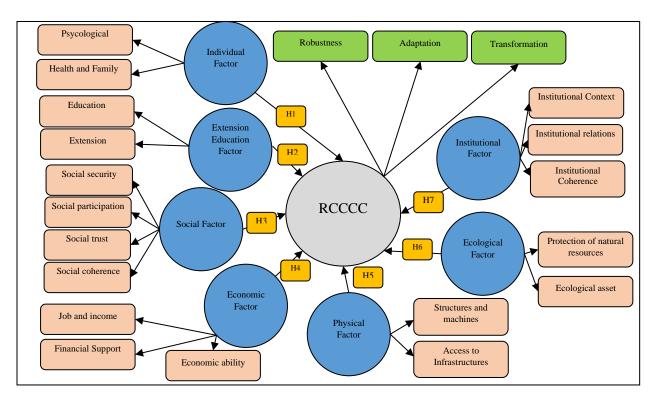

Figure 1. Conceptual model of the research (authors).

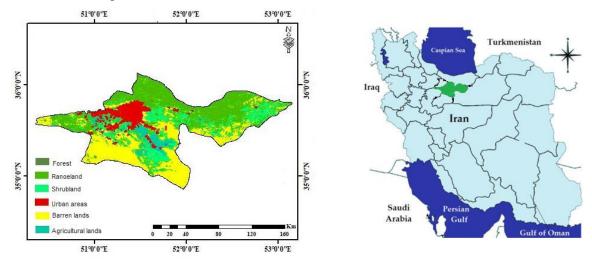

Materials and Methods

Study area

Tehran Province is located in the northern half of Iran (Figure 2). It has three elevation zones and an annual rainfall ranging from 230 to 500 mm. The largest area, accounting for 40.51 percent, is

In Press, Pre-Proof Version

designated for rangeland use. Additionally, the majority of the province, at 49.56 percent, is classified as having a semi-arid climate (Javadi et al., 2024).

convergent validity.

Figure 2. Study area (Javadi et al., 2024)

Research methodology

The present study employed a survey method to analyze the factors affecting the resilience of pastoralists in Tehran province under CC conditions. The statistical population of this study consists of the 5584 pastoralists in Tehran province as of 2024, according to the avaiable statistics. To estimate the sample size from this population we utilized the Cochran formula, selecting a total of 318 individuals through stratified random sampling, taking into account the existing strata (counties). To measure the factors affecting PRCC conditions, we developed a researcher-made questionnaire with response options based on the Likert scale. Dtat analysis was conducted using SMART PLS and SPSS software. To ensure the validity of the research instrument, the questionnaire was reviewed by subject matter experts and specialists in natural resources. Their feedback was incorporated, leading to necessary revisions and confirming the validity of the questionnaires. To determine the reliability of the research tool, Cronbach's alpha coefficient was calculated for each section of the questionnaire, indicating the appropriate internal consistency of the items and the stability of the questionnaire.

To validate the measurement model (Table 1), we found that the composite reliability (CR) and average variance extracted (AVE) were both above 0.7, suggesting solid internal consistency

among the model's variables. The AVE value exceeding 0.5 for the variables indicates acceptable

In Press, Pre-Proof Version

Table 1. Reliability and Convergent Validity in the Measurement Model.

Constructs	Cronbach Alpha	Convergent validity	Composite Reliability (CR)	Average Variance Extracted
1. Individual Factor	0.782	0.792	0.873	0.697
2. Educational and Extensional	0.777	0.888	0.840	0.534
Factor				
3. Social Factor	0.860	0.909	0.897	0.527
4. Economic Factor	0.870	0.912	0.903	0.626
5. Physical Factor	0.831	0.870	0.874	0.564
6. Ecological Factor	0.737	0.774	0.787	0.525
7. Institutional Factor	0.820	0.894	0.868	0.652
8. Robustness	0.823	0.826	0.883	0.654
9. Adaptability	0.777	0.779	0.857	0.599
10. Transformability	0.812	0.815	0.877	0.642

To examine the discriminant validity of the measurement model, the Fornell and Larcker criterion was employed. According to Tables 2 and 3, the square root of AVE for each construct in the present study is greater than the correlations among them; therefore, it can be concluded that the model constructs have stronger association with their own indicators than with the indicators of other constructs. In other words, the discriminant validity of the model is considered to be at an acceptable level.

 Table 2. Fornell-Larcker Criterion.

7. Institutional Factor	0.686	0.658	0.692	0.768	0.685	0.680	0.807

Research findings

The age range of the sample studied was 26 to 70 years. The mean age was 23.46 years, and the standard deviation was 88.9. The median age was 47 years, and the mode was 45 years. In terms of gender, 1.3% of the respondents with a frequency of 4 were women, while 98.7% with a frequency of 314 were men. In terms of education level, the most frequenctly level of education

In Press, Pre-Proof Version

was a high school diploma. The median work experience among the participants was 20 years. The most common types of livestock owned by of Pastoralists were sheep, goats, cows, and camels.

The measurement model

To examine the causal relationships between observed variables and latent variables, confirmatory factor analysis was used. Figure 3 illustrates the measurement model of PRCC conditions based on factor loadings and t-values. If t-values exceed 1.96, it indicates the significance of the corresponding variable (Vinzi et al., 2010).

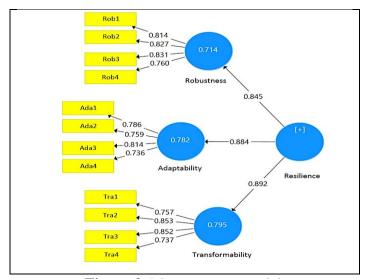

Figure 3. Measurement model.

As can be seen in Table 4, factor load values of indicators are more than 0.4; that is, the variance of indicators with their related construct was acceptable, indicating the suitability of indicators for measuring the latent variables of PRCC conditions. Also, the significance of all indicators is greater than 1.96, indicating a meaningful correlation between indicators and latent variables of PRCC conditions (Vinzi et al., 2010).

Structural Model Fit

Figure 4 presents the research structural model based on the t-values. Since the t-values for all paths exceed 1.96, this indicates that all paths are significant, confirming the research hypotheses at the 95 percent confidence level.

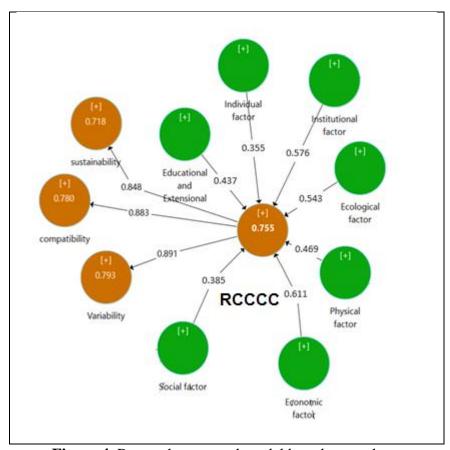

Figure 4. Research structural model based on t values.

The R² value for the construct of PRCC was calculated as 0.755. Considering the benchmark values, this confirms the fitness of the structural model. The effect size criterion (f²) for all constructs is greater than 0.02, indicating an average effect of the independent variables in the study. Additionally, the stone-geisser criterion or Q² for endogenous variables exceeds the threshold of 0.35, demonstating strong predictive power for the model and confirming the appropriate fit of the structural model. According to the software output, the redundancy criterion for PRCC conditions is 0.568. The indicator of communalities, derived from the average factor loadingss of each latent endogenous factor, is positive. This reflects the quality of the measurement model of latent variables. The overall fit of the model was evaluated using a single criterion known

In Press, Pre-Proof Version

as the Goodness of Fit (GOF). In this study, the GOF was found to be 0.559, indicating a strong overall fit for the model.

The results of testing the research hypotheses with reference to Figure 3 are presented in Table 6.

The results show that individual, educational and extensional, social, economic, physical,

ecological and institutional factors have a significant and positive effect on PRCC, and improving

them will lead to enhancing PRCC conditions.

Natural resources policymakers are concerned that, given the critical conditions arising from climate changes and recent droughts, no appropriate program and actions have been taken to reduce vulnerability and enhance the resilience of pastoralists, this is the gap that has always been existed. Furthermore, the actions taken to improve resilience have often resulted in the misallocation of significant resources. Therefore, analysing the factors the influence resilience was one of the primary objectives of this study, which aimed to enhance the resilience of pastoralists. Based on this, the present study aimed to analyze the factors affecting resilience from the perspective of Tehran province pastoralists under climate change conditions. Consequently, seven individual, educational and extensional, social, economic, physical, ecological and institutional factors were investigated. According to the literature review, the individual factor included psychological indicators, health and family dynamics. The educational and extension factor encompassed indicators related to education and extension services. The social factor was defined by indicators of social security, participation, trust and coherence. The economic factor involved measures of employment and income, financial support and economic capacity. The physical factor included indicators related to access to infrastructure, structures and machinery. The ecological factor focused on ecological assets and the protection of natural resources. Lastly, the

In Press, Pre-Proof Version

259	institutional factor comprised indicators of institutional context, institutional relations and
260	institutional coherence. Robustness, adaptation and transformability were identified as outcomes
261	of resilience and were investigated.
262	In this study, seven hypotheses were formulated and tested using structural equation modeling
263	with Smart PLS software. The impact analysis revealed path coefficients and significance values
264	for the individual (0.355, 5.849), educational and extension (0.437, 8.516), social (0.385, 6.273),
265	economic (0.611, 13.643), physical (0.469, 8.928), ecological (0.543, 10.137) and institutional
266	(0.576, 11.422) factors. This indicates that the seven aforementioned factors have a positive and
267	significant effect on PRCC conditions with 95 percent confidence. This finding is consistent with
268	some studies (Adzawla et al., 2020; Melketo et al., 2021; Ahmad and Afzal et al., 2021; Le Goff
269	et al., 2022; Kapruwan et al., 2024).
270	The R ² value for the construct of PRCC was calculated as 0.755, considering the benchmark
271	values, confirming the fitness of the structural model. The GoF (0.559) criterion value indicated
272	that the overall quality of the model is strong and the overall model of the study is an appropriate
273	model. Therefore, the need to pay more attention to the model is felt.
274	The second part of the model was dedicated to ranking the factors affecting PRCC conditions. The
275	findings showed that the economic factor with a value of 0.611, the institutional factor with a value
276	of 0.576, the ecological factor with a value of 0.543, the physical factor with a value of 0.469, the
277	educational and extension factor with a value of 0.437, the social factor with a value of 0.385, and
278	the individual factor with a value of 0.355 have significant and positive effects on PRCC conditions
279	respectively.they directly explain 75.5 percent of the changes related to the variable of PRCC
280	conditions.
281	Considering the results of the second dimension, there is an increasing need to pay more attention
282	to economic, ecological, and institutional factors. Attention to economic factor has been noted in
283	some studies (Adzawla et al., 2020; Melketo et al., 2021; Ahmad and Afzal et al., 2021; Le Goff
284	et al., 2022; Kapruwan et al., 2024). However, Le Goff et al. (2022) and Kapruwan et al. (2024)
285	have stated other priorities for strengthening the resilience of communities to CC.
286 287	Conclusion

Conclusion

This research was carried out in one of the key regions of Iran to explore the factors influencing 288 pastoralists' resilience to CC. Identifying appropriate measures to enhance pastoralists' resilience 289

In Press, Pre-Proof Version

to CC can improve their adaptability to crises, thereby preventing rangeland degradation and
migration of pastoralists. Obviously, it is necessary to focus on increasing the resilience levels of
Pastoralists in the region within the context of CC. Accordingly, this study has attempted to
identify resilience measures and analyze them in the form of seven hypotheses and models. Former
findings have pointed out some of the factors affecting resilience. In this study, a new and
comprehensive interpretation of the factors has been considered via combination of the previous
findings. They've been added to the existing body of knowledge in this field. The findings of this
study indicated the significant effect of these factors on improving the resilience of the studied
pastoralists. Economic, Institutional and Ecological factors are the most important ones affecting
them. Drought affects vegetation and makes it difficult for pastoralists to meet basic needs.
Government financial and technical support can protect livelihoods during times of crisis and
increase resilience. Given these results, the following suggestions are made to enhance the
resilience of pastoralists in the face of CC:
- Government managers and planners must pay special attention to the economic factor in order to
enhance resilience and support pastoralists. At a lower level, it was determined that increasing
resilience necessitates strengthening the economic capacity, which includes the ability to purchase
food for households during times of need. This group operates within a dependent and vulnerable
economy, and the distribution of water and food by government agencies can help meet basic needs
and mitigate the impact of crises.
-Managers of government departments should provide the necessary infrastructure to strengthen
institutional relationships through the interaction of pastoralists with experts and specialists. This
approach will lead to greater familiarity, recognition, and improved decision-making regarding the
cultivation of suitable plants, optimal range management, and transitioning livelihoods from
livestock to other oportunities, including beekeeping, ecotourism, etc. furthermore, Strengthening
trade associations and cooperative unions with economic, institutional, and legal support can
enhance coordination and cooperation between departments and institutions, thereby blostering
Institutional solidarity.
- It is essential to raise the awareness, knowledge, and attitudes of pastoralists to improve
ecological assets. Capacity building in livestock management and rehabilitation efforts in
rangelands can enhance plant cover, preserve soil quality and quantity, and prevent soil erosion,
all of which are crucial for supporting pastoralists during drought years.

In Press, Pre-Proof Version

- In this study, variations in rangeland cover, climate, and livestock types were observed. This
- indicates that pastoralists in this region do not form a homogeneous group. This variability may
- have affected the responses of pastoralists and represents a limitation of the research. Future
- 324 studies should take these factors into account.
- 325 Since the factors affecting resilience vary across countries, the results of this study should be
- generalized with caution to other regions that are less similar to this area.

تحلیل عوامل موثر بر تابآوری مرتعداران در شرایط تغییر اقلیم

امیرکیوان درویش، مریم امیدی نجف آبادی، سیدمهدی میردامادی، و سیدجمال فرجاله حسینی

چکیده

پدیده تغییر اقلیم یکی از بزرگترین چالشهای عصر حاضر است که مراتع را در مقیاس جهانی و منطقهای تحت تاثیر قرار داده است. افزایش آسیبپذیری در میان مرتعداران، اهمیت تمرکز بر تفکر تابآوری را نشان میدهد. تابآوری مرتعداران به ظرفیت کسب و کارهای مرتعداری در مواجهه با تهدیدها یا چالشها، بصورت مقاومت، سازگاری و تغییرپذیری است. این پژوهش با هدف کلی تحلیل عوامل موثر بر تابآوری از دیدگاه مرتعداران استان تهران در شرایط تغییر اقلیم انجام شد. این پژوهش از نظر هدف کاربردی و روش شناسی اکتشافی بود. نمونه مورد مطالعه شامل 317 مرتعدار بود که به روش نمونهگیری تصادفی طبقهای انتخاب شدند. برای گردآوری دادهها، از پرسشنامه محقق ساخته استفاده شد. روایی پرسشنامه با استفاده از میانگین واریانس استخراج شده و پایایی آن از طریق محاسبه پایایی ترکیبی و آلفای کرونباخ تعیین شد. دادهها با استفاده از تکنیک مدل سازی معادلات ساختاری با نرم افزار Smart PLS مورد تجزیه و تحلیل قرار گرفت. نتایج نشان داد که عوامل فردی، آموزشی و ترویجی، اجتماعی، اقتصادی، فیزیکی، اکولوژیکی و نهادی بر تابآوری مرتعداران تحت شرایط تغییر اقلیم رابطه معنادار دارند. این عوامل 75.5 درصد تابآوری مرتعداران را در شرایط تغییر اقلیم تبیین کردند.
